

Section 33

Veterans Affairs Adjustment

Purpose: A Department of Veterans Affairs (VA) policy led to underreporting of cases to some SEER registries for diagnosis years 2005 through 2008, primarily among adult males. Assuming that proportions of cancer cases among males diagnosed by VA hospitals follow similar patterns over time, correction factors can be estimated for age-adjusted incidence rates in SEER-9 and SEER-17 regions.

Data for Analysis: VA underreporting correction factors were estimated for SEER 9 and SEER 17 groupings. Data to estimate VA underreporting were provided by these SEER-9 registries: San Francisco-Oakland, Iowa, New Mexico, Seattle, and Atlanta. Connecticut, Hawaii, Utah, and Detroit opted not to share VA case counts when reporting known VA cases. SEER-17 registries with data included San Jose-Monterrey, Los Angeles, Rural Georgia, Louisiana, and Greater California. Kentucky provided partial data. The Alaskan Native and New Jersey registries opted not to share VA case counts while reporting known VA cases. Of nine registries with usable data, VA underreporting was most pronounced for New Mexico and Los Angeles with some underreporting in Greater California, San Jose-Monterrey, and Iowa and relatively complete reporting in San Francisco-Oakland, Seattle-Puget Sound, Metropolitan Atlanta, and Louisiana.

Analytic Approach: Correction factors for male cases diagnosed from 2005 through 2008 were estimated with VA hospital data from 2000 through 2003: Correction factor= (1-Reported VA only cases/All reported cases)/(1-expected proportion VA only cases)

The 2010 submission file is the first to include diagnosis year (DY) 2008. The expected proportion of cases reported only by the VA for DY 2008 in submission year (SY) 2010 is estimated from data on VA only cases for leading cancers of men, in years before VA reporting changed (e.g., DY 2000 through 2003, SY 2002 through 2005):

$$[\text{VA only (DY 2000, SY 2002)} + (\text{DY 2001, SY 2003}) + (\text{DY 2002, SY 2004}) + (\text{DY 2003, SY 2005})] / [\text{(All cases (DY 2000, SY 2002)} + (\text{DY 2001, SY 2003}) + (\text{DY 2002, SY 2004}) + (\text{DY 2003, SY 2005})]$$

Underreporting of VA cases in preceding DYS 2005, 2006, and 2007 were also estimated from VA only case proportions reported in the baseline SYs (Figure 1).

Figure 1. Matrix of VA only case proportions by submission & diagnosis year

	Diagnosis Year									
	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009
Submission Year	2002	1st								
2003	2nd	1st								
2004	3rd	2nd	1st							
2005	4th	3rd	2nd	1st						
2006		4th	3rd	2nd						
2007			4th	3rd						
2008				4th						
2009										
2010	2010 Submission File				4th	3rd	2nd	1st		

Overall and Age- and Race-Specific VA Correction Factors: VA-adjusted correction factors for males in SEER 9 and SEER 13 Registries were estimated based on available VA underreporting data. Correction factors were calculated for All Races, Whites, and Blacks. These correction factors were estimated for all age groups combined, and further parsed for four age-specific groups: 0-24, 25-49, 50-74, and 75+ years of age.

VA Reporting Backlog and Delay Adjustment: Typically, most cases diagnosed by a VA hospital are expected to be reported in the first possible data submission year, with a small proportion of delayed case reporting in subsequent submission years. Because some VA-reporting has resumed since VA underreporting first occurred the resulting backlog of VA case could create a surveillance artifact affecting delay-adjusted models. The VA cases from diagnosis years 2005 through 2007 were therefore redistributed in the 2010 submission file to reflect the expected delay distribution. VA delay-adjustments were integrated into SEER 9 and SEER 13 delay-adjusted models as described in the CSR technical notes at http://seer.cancer.gov/csr/1975_2008/technotes/reportingdelay.html and in an elaboration on the methods at <http://surveillance.cancer.gov/delay/vabacklog.html>.

VA Underreporting Effect on Trends: Effects of correction for VA underreporting on delay-adjusted incidence trends were modest (Table 1). After VA-adjustment a new segment was added to one of 15 delay-adjusted Joinpoint models: All Sites Combined (Black Race). The number of Joinpoint segments, their direction and statistical significance remained consistent for seven other Joinpoint models: All Sites Combined (All Races, White Race), cancers of the Prostate, Lung and Bronchus, Colon and Rectum, Kidney and Renal Pelvis, and Pancreas. Delay-adjusted Joinpoint models remained unchanged after VA adjustment for the remaining seven sites: Urinary Bladder cancer, Melanoma, Non-Hodgkin lymphoma, Leukemia, cancer of the Oral Cavity and Pharynx, Stomach, and Liver and Intrahepatic Bile Duct.

Estimation of Missing VA Cases: The VA correction factors for all cancers combined among males (All Races, Whites, Blacks) in SEER 9 and SEER 17 registries during diagnosis years 2006 to 2008 are listed for all age groups and four age-specific groups (Table 2). Most correction factors were larger for DY 2008 than previous reporting years, for Blacks compared to Whites, and for men 50-74 and 75+ compared to younger aged men. Cancer-site specific correction factors for All Races, Whites and Blacks are presented in Tables 3 to 14 in descending order of incidence rates. Correction factors were consistent with those for All Cancer Sites Combined for Prostate (Table 3), Lung and Bronchus (Table 4), Colon and Rectum (Table 5), Urinary Bladder (Table 6), and Melanoma of the Skin (Table 7). Correction factors for Black males in the 75+ year age group appeared to be slightly greater than the overall VA correction factor in DY 2008 for non-Hodgkin lymphoma (Table 8) and 2007 for Kidney and Renal Pelvis (Table 9) and Leukemia (Table 10). VA correction factors for Black males 50-74 years of age were greater than the all cancer combined VA correction factor in DY 2008 for Oral and Pharynx (Table 11) and Pancreas cancer (Table 12). While VA-correction factors for Stomach Cancer were similar to overall correction factors (Table 13), those for Intrahepatic Bile Duct and Liver Cancer were elevated among Black males, ages 50-74 years, from DY 2006 to 2008 (Table 14).

VA Underreporting adjustment analyses are computed by age (0-24, 25-49, 50-74, 75+), race (all races, White, Black) and cancer site.

* SEER 9 Registries: Connecticut, Hawaii, Iowa, Utah, and New Mexico, metropolitan San Francisco, Detroit, Atlanta, and Seattle-Puget Sound.

Correction factors apply to the November 2010 SEER data submission.

†Joinpoint analyses with up to five joinpoints are based on rates per 100,000 persons and were age-adjusted to the 2000 US standard population (19 age groups – Census p25–1130).

Joinpoint (JP) Regression Program, v 3.5. April 2011, National Cancer Institute.

‡APC is based on delay-adjusted rates that were age-adjusted to the 2000 US standard population (19 age groups – Census p25–1130).

§APC is statistically significantly different from zero ($P<.05$, two-sided Student t -test.).

|| APCs are same as delay-adjusted.
