DIGESTIVE AND HEPATOBILIARY SYSTEMS

DIGESTIVE SYSTEM SITES

Below is information about the subsites of the colon

- The *ascending colon*, measuring 15 to 20 cm, begins with the *cecum*, a 6 to 9 cm pouch that arises at the proximal segment of the right colon at the end of the terminal ileum. It is covered with a visceral peritoneum (serosa) and measures 15 to 20 cm. The ascending colon ends at the *hepatic flexure*, which transitions the ascending colon into the *transverse colon*, passing just inferior to the liver and anterior to the duodenum.

- The *transverse colon*, measuring 18 to 22 cm long, is completely intraperitoneal and supported on a mesentery that is attached to the pancreas. Anteriorly the serosa is continuous with the gastrocolic ligament. The transverse colon ends at the *splenic flexure*, which transitions into the *descending colon*.

- The *descending colon*, measuring 10 to 15 cm long, passes interiorly to the spleen and anterior to the tail of the pancreas. The posterior aspect lacks serosa and is in direct contact with the retroperitoneum.

- The *sigmoid colon*, measuring 15 to 20 cm long, is completely intraperitoneal with a mesentery that develops at the medial border of the left psoas major muscle and extends to the *rectum*. The transition from the sigmoid colon to the rectum is marked by the fusion of the taenia of the sigmoid colon to the circumferential muscle of the rectum.

- The *rectum*, measuring 12 to 16 cm, is covered by peritoneum in front and on both sides.

1. Subserosal tissues include fat and flesh between the muscularis and the serosa.
2. Serosa is also called mesothelium and visceral peritoneum. For the stomach and small intestine, serosa is also referred to as tunica serosa. The term “serosa” is sometimes generically used to include both the serosa and the subserosa, and therefore, the clinician should be consulted to determine if the use of “serosa” includes the subserosa also.
3. Mesenteric fat is also called pericolic fat.
4. The tissue outside the muscularis of the esophagus is composed of fibrous connective tissue and referred to as adventitia.
5. Anterior and lateral, but not posterior.
6. Referred to as perirectal tissue.
DISTINGUISHING “IN SITU” AND “LOCALIZED” TUMORS FOR THE DIGESTIVE SYSTEM

1. Historically, carcinomas described as “confined to mucosa” have been assigned 1 (localized). In order to provide greater specificity and to rule out the possibility of classifying noninvasive tumors in this category, abstractors should determine
   a. If the tumor is confined to the epithelium, in which case it is in situ, OR
   b. If the tumor has penetrated the basement membrane to invade the lamina propria, in which case it is localized and assigned Summary Stage 1 (localized) for invasion of the lamina propria

2. The layers of the digestive tract consist of
   a. The EPITHELIAL LAYER borders on the lumen. It contains no blood vessels or lymphatics
   b. The BASEMENT MEMBRANE, a sheet of extracellular material, functions as a filtration barrier and a boundary involved in generating and maintaining tissue structure
   c. The LAMINA PROPRIA, composed of areolar connective tissue, contains blood vessels, nerves, and, in some regions, glands. Once tumor has broken through the basement membrane into the lamina propria, it can spread by way of the lymphatics and blood vessels to other parts of the body
   d. The MUSCULARIS MUCOSAE is a thin layer of smooth muscle fibers. It is found in the wall of the digestive tract from the esophagus to the anal canal
   e. The SUBMUCOSA is a thick layer of either dense or areolar connective tissue. It contains blood vessels, lymphatic vessels, nerves, and, in some regions, glands
   f. The MUSCULARIS PROPRIA is a double layer of muscle tissue in most of the digestive tract; it constitutes the wall of the organ.
   g. The SEROSA, the outermost layer covering most of the digestive tract, is a single layer of squamous epithelial cells, part of the visceral peritoneum.
   h. The SUBSEROSA is inside the serosa (mesothelium), and sometimes part of the serosa. The serosa and subserosa are present only in the peritonealized portions of the digestive tract.
      i. For the esophagus and in the rectum below the peritoneal reflection, there is no serosa
      ii. For the esophagus, the connective tissue of surrounding structures merges with the connective tissue of the esophagus and is called ADVENTITIA.

Note 3: Cancers involving the EGJ that have their epicenter within the proximal 2 cm of the cardia (Siewert types I/II) are to be staged as esophageal cancers (see the Esophagus (excluding GIST) chapter). Cancers whose epicenter is more than 2 cm distal from the EGJ, even if the EGJ is involved, will be staged using the stomach cancer chapter.

- The Schema Discriminator EsophagusGEJunction (EGJ)/Stomach is used to discriminate between EsophagusGEJunction and Stomach which are coded to ICD-O-3 code C160
Note 4: Non-invasive carcinomas in the esophagus formerly called in situ are now called high grade dysplasia. High grade dysplasia and severe dysplasia are generally not reportable in cancer registries.

- Code 0 if your registry collects these tumors

Note 3: If a tumor involves the esophagogastric junction (EGJ) and its epicenter is less than or equal to 2 cm into the proximal stomach (i.e. less than or equal to 2 cm distal to the EGJ), use the esophageal cancer chapter for summary stage (see the Esophagus (excluding GIST) chapter). Tumors involving the EGJ with their epicenter >2 cm into the proximal stomach (i.e., >2cm distal to the EGJ) are now classified using the stomach chapter. Cardia cancers that do not invade the EGJ should be classified based on the stomach cancer chapter for summary stage.

- Schema Discriminator 1: EsophagusGEJunction (EGJ)/Stomach is used to discriminate between EsophagusGEjunction and Stomach which are coded to ICD-O-3 code C160.

- Collaborative Stage Data Collection System, version 02.05: https://cancerstaging.org/cstage/Pages/default.aspx

**Note 2:** See the following chapters for the listed histologies

- 8710-8714, 8800-8934, 8940-9138, 9141-9582: *Soft Tissue*
- 8935-8936: *GIST*
- 9140: *Kaposi Sarcoma*
- 9700-9701: *Mycosis Fungoides*

**Note 3:** Code 0 (behavior code 2) includes cancer cells confined within the glandular basement membrane (intraepithelial), or described as in situ.
Note 4: For the following, AJCC 8th edition stages these as in situ tumors. SS2018 stages these as localized (behavior code 3)

- Intramucosal, NOS
- Lamina propria
- Mucosa, NOS
- Confined to, but not through muscularis mucosa

Note 5: Ignore intraluminal extension to adjacent segment(s) of colon/rectum or to the ileum from the cecum; code depth of invasion or extracolonic spread as indicated.

Note 6: The colon and rectum may be entirely peritonealized, partially peritonealized, or non-peritonealized. Use this list to help distinguish between localized and regional Tumors (See Note 7).

- Entirely peritonealized segments: Cecum, Transverse colon, Sigmoid colon, Rectosigmoid colon
- Segmental surfaces that are peritonealized: Anterior and lateral surfaces of: Ascending colon, Descending colon, Hepatic flexure, Splenic flexure, Upper third of rectum. Anterior surface: Middle third of rectum.
- Entirely non-peritonealized segment: Lower third of rectum
- Segmental surfaces that are non-peritonealized: Posterior surface of: Ascending colon, Descending colon, Hepatic flexure, Splenic flexure, Upper two-thirds of rectum

Note 7: Invasion into “pericolonic/pericolorectal tissue” can be either localized (code 1) or regional (code 2), depending on the primary site and whether it is peritonealized (fully or partially) or not. When extension is described as “pericolonic/pericolorectal tissue”

- Localized may NOT be used for entirely peritonealized sites (cecum, transverse colon, sigmoid colon, rectosigmoid colon), as this would be equivalent to peritonealized pericolic/perirectal tissue invasion (regional, code 2)
- Localized may ONLY be used for peritonealized sites (See Note 6) when the extension is described using other terms listed under localized (code 1) (ex. subserosal fat). If there are no other terms used to describe the extension, other than invasion of “pericolonic tissue”, then assign regional (code 2)
- For partially peritonealized sites (See Note 6), “pericolonic/pericolorectal tissue” may indicate invasion of either non-peritonealized (localized, code 1) or peritonealized tissue (regional, code 2)
  o Check for mention of serosa/peritoneum in the operative report and/or pathology report final diagnosis or gross description to determine the correct code. Again, if other descriptions besides “pericolonic/pericolorectal tissue” are used, assign localized (code 1) or regional (code 2) based on the terminology used
- If the pathologist does not further describe the “pericolic/perirectal tissues” as either “non-peritonealized pericolic/perirectal tissues” vs “peritonealized pericolic/perirectal tissues” and the operative report and/or gross description does not describe the tumor...
relation to the serosa/peritoneal surface, and it cannot be determined whether the tumor arises in a peritonealized portion of the colon, code localized (code 1).

**Note 8:** Tumor that is adherent to other organs or structures, macroscopically, is coded as regional (code 2) or distant (code 7). However, if no tumor is present in the adhesion, microscopically, the classification should be coded to localized (code 1) or regional (code 2).

**Note 9:** Tumors characterized by involvement of the serosal surface (visceral peritoneum) by direct extension or perforation in which the tumor cells are continuous with the serosal surface through inflammation are coded to regional (code 2).
